Outline

The problem

ODE examples

ODEs

Euler's method

Backward Euler

Stability

The problem

- Given

$$y' = f(t, y), \quad y(a) = c$$

compute $y(t)$ on $[a, b]$

- $y' \equiv y'(t) \equiv \frac{dy}{dt}$
- This is an Initial Value Problem (IVP) in Ordinary Differential Equations (ODEs)
- We approximate $y(t)$ at points t_i in $[a, b]$ using a numerical method

ODE examples

$$y' = -y + t$$

- Solution is $y(t) = t - 1 + \alpha e^{-t}$:

$$\begin{aligned}y'(t) &= 1 - \alpha e^{-t} \\ -y + t &= -(t - 1 + \alpha e^{-t}) + t = 1 - \alpha e^{-t}\end{aligned}$$

- Given $y(0) = c$, e.g. $c = 5$,

$$y(0) = -1 + \alpha = c = 5, \quad \alpha = 6$$

$$y(t) = t - 1 + 6e^{-t}$$

is the solution with this initial condition

Motion of a pendulum

$$\theta'' = -g \sin \theta, \quad \theta'' = \frac{d^2\theta(t)}{dt^2}$$

- ball of mass 1 attached to the end of a rigid, massless rod of length $r = 1$
- $g \approx 9.81$ is gravity
- t is time
- This is a second-order ODE. To write as a first-order ODE, set $y_1 = \theta$, $y_2 = \theta' = y_1'$:

$$y_1' = y_2$$

$$y_2' = -g \sin(y_1)$$

- Needed initial conditions are $y_1(0)$ and $y_2(0)$

ODEs

System of n first-order equations in n variables

$$y' = f(t, y), \quad f : \mathbb{R} \times \mathbb{R}^n \rightarrow \mathbb{R}^n$$

Nonlinear: if f is nonlinear in y , linear otherwise

Autonomous ODE

$$y' = f(y), \quad y(a) = c$$

is an autonomous ODE, does not depend on time explicitly

$$y' = f(t, y), \quad y(a) = c$$

is non-autonomous

To convert a non-autonomous ODE to an autonomous set $x = t$ and then

$$x' = 1$$

$$y' = f(x, y), \quad x(a) = a, \quad y(a) = c$$

Set $z = (z_1, z_2)^T = (x, y)^T$. Then $z' = f(z)$:

$$z'_1 = 1$$

$$z'_2 = f(z)$$

High-order ODEs

$$y^{(n)} = f\left(t, y, y', \dots, y^{(n-1)}\right)$$

can be converted to first-order by setting

$$y_1 = y$$

$$y_2 = y' = y_1'$$

$$y_3 = y'' = y_2'$$

$$\vdots$$

$$y_n = y^{(n-1)} = y_{n-1}'$$

Then

$$y_1' = y_2$$

$$y_2' = y_3$$

$$\vdots$$

$$y_n' = f(t, y_1, y_2, \dots, y_n)$$

To solve, we need initial values for

$$y_1(a), y_2(a), \dots, y_n(a)$$

Euler's method

- Let $h = (b - a)/N$, $N > 1$ is an integer
- h is stepsize
- Let $t_0 = a$, $t_i = a + ih$, $i = 0, 1, \dots, N$
- From $y'(t_i) = f(t_i, y(t_i))$, we write

$$\begin{aligned}y(t_{i+1}) &= y(t_i) + hy'(t_i) + \frac{h^2}{2}y''(\xi_i), \quad \xi_i \text{ between } t_i \text{ and } t_{i+1} \\&= y(t_i) + hf(t_i, y(t_i)) + \frac{h^2}{2}y''(\xi_i) \\&\approx y(t_i) + hf(t_i, y(t_i))\end{aligned}$$

- Euler's method:

$$y_0 = c$$

$$y_{i+1} = y_i + hf(t_i, y_i), \quad i = 0, 1, \dots, N-1$$

- Example: Euler's method on $y' = -y + t$, $y(0) = y_0 = 5$, with $h = 0.1$:

$$y_{i+1} = y_i + hf(t_i, y_i) = y_i + h(-y_i + t_i)$$

$$y_1 = y_0 + h(-y_0 + t_0) = 5 + 0.1(-5 + 0) = 4.5$$

$$y_2 = y_1 + h(-y_1 + t_1) = 4.5 + 0.1(-4.5 + 0.1) = 4.06$$

$$y_3 = y_2 + h(-y_2 + t_2) = 4.06 + 0.1(-4.06 + 0.2) = 3.674$$

- Exact solution is $y(t) = t - 1 + 6e^{-t}$
- The corresponding exact values are $y(0.1) \approx 4.5290$,
 $y(0.2) \approx 4.1124$, $y(0.3) \approx 3.7449$

Example: Forward Euler on $y' = -y + t$ 

Backward Euler

- We can write

$$\begin{aligned}y(t_i) &= y(t_{i+1}) - hy'(t_{i+1}) + \frac{h^2}{2}y''(\eta_i) \\&\approx y(t_{i+1}) - hf(t_{i+1}, y(t_{i+1})) \\y(t_{i+1}) &\approx y(t_i) + hf(t_{i+1}, y(t_{i+1}))\end{aligned}$$

- Backward Euler

$$y_{i+1} = y_i + hf(t_{i+1}, y_{i+1})$$

- This is an implicit method; forward Euler is explicit

- Example: Backward Euler method on $y' = -y + t$, $y(0) = y_0 = 5$, with $h = 0.1$:

$$\begin{aligned}y_{i+1} &= y_i + hf(t_{i+1}, y_{i+1}) \\ &= y_i + h(-y_{i+1} + t_{i+1})\end{aligned}$$

- We need to solve for y_{i+1} :

$$\begin{aligned}y_{i+1} &= y_i - hy_{i+1} + ht_{i+1} \\ y_{i+1} + hy_{i+1} &= y_i + ht_{i+1} \\ y_{i+1} &= \frac{y_i + ht_{i+1}}{1 + h}\end{aligned}$$

- We compute

$$y_1 = \frac{y_0 + ht_1}{1 + h} = \frac{5 + 0.1 \cdot 0.1}{1 + 0.1} \approx 4.5545$$

$$y_2 = \frac{y_1 + ht_2}{1 + h} \approx \frac{4.5545 + 0.1 \cdot 0.2}{1 + 0.1} \approx 4.1586$$

$$y_3 = \frac{y_2 + ht_3}{1 + h} \approx \frac{4.1586 + 0.1 \cdot 0.3}{1 + 0.1} \approx 3.7987$$

- The corresponding exact values are $y(0.1) \approx 4.5290$, $y(0.2) \approx 4.1124$, $y(0.3) \approx 3.7449$
- Here it was easy to solve for y_{i+1} : $f(t, y) = -y + t$ is linear in y
- In general, it is non-linear: apply Newton's method

Example: FE and BE on $y' = -y + t$ 

Stability

Forward Euler

- Consider $y' = \lambda y$, $y(0) = y_0$
- The exact solution is $y(t) = e^{\lambda t} y_0$
- Forward Euler with constant stepsize h is

$$\begin{aligned}y_{i+1} &= y_i + hf(t_i, y_i) = y_i + h\lambda y_i \\&= (1 + h\lambda)y_i \\&= (1 + h\lambda)^2 y_{i-1} \\&\vdots \\&= (1 + h\lambda)^{i+1} y_0\end{aligned}$$

- If $\lambda < 0$, $y(t)$ is decaying. Since $|y(t_{i+1})| < |y(t_i)|$, we want $|y_{i+1}| \leq |y_i|$

Stability cont.

- For the method to be numerically stable, we require

$$|y_{i+1}| = |1 + h\lambda| \cdot |y_i| \leq |y_i|$$

- That is $|1 + h\lambda| \leq 1$, or

$$-1 \leq 1 + h\lambda \leq 1$$

$$-2 \leq h\lambda \leq 0$$

$$h \leq \frac{2}{|\lambda|}$$

- If $|\lambda|$ is large, we can have a severe restriction on the stepsize
If e.g. $y' = -10^6 y$, $h \leq 2 \cdot 10^{-6}$

Stability cont.

Example 1.

- Consider $y' = -10y$, $y(0) = y_0$
- Euler's method is

$$y_{i+1} = y_i + h\lambda y_i = (1 - 10h)y_i$$

- For stability $h \leq 0.2$
- If e.g. $h = 0.21$ then

$$y_1 = (1 - 10 \cdot 0.21)y_0 = -1.1y_0$$

$$y_2 = -1.1y_1 = 1.21y_0$$

$$y_3 = -1.1y_2 = -1.331y_0$$

$$\vdots$$

$$y_i = (-1.1)^i y_0$$

Stability

Example 1. cont.

Stability

Backward Euler

- Consider the backward Euler on $y' = \lambda y$, where $\lambda < 0$

$$y_{i+1} = y_i + h\lambda y_{i+1}$$

$$y_{i+1} = \frac{1}{1 - h\lambda} y_i$$

$$\begin{aligned} |y_{i+1}| &= \frac{1}{|1 - h\lambda|} |y_i| \\ &\leq |y_i| \quad \text{for any } h > 0 \end{aligned}$$

Stability

Example 2.

- $y' = -10y$
- Backward Euler is

$$y_{i+1} = \frac{1}{1 + 10h} y_i$$

- Stable for any $h > 0$
- Backward Euler is absolutely (for any $h > 0$) stable

Stability

Example 2. cont.
